Definition of Data Center

Data Center: A Facility that houses, access and processes data to produce information

Data is raw, unorganized facts that need to be processed. Data can be something simple and seemingly random and useless until it is organized.

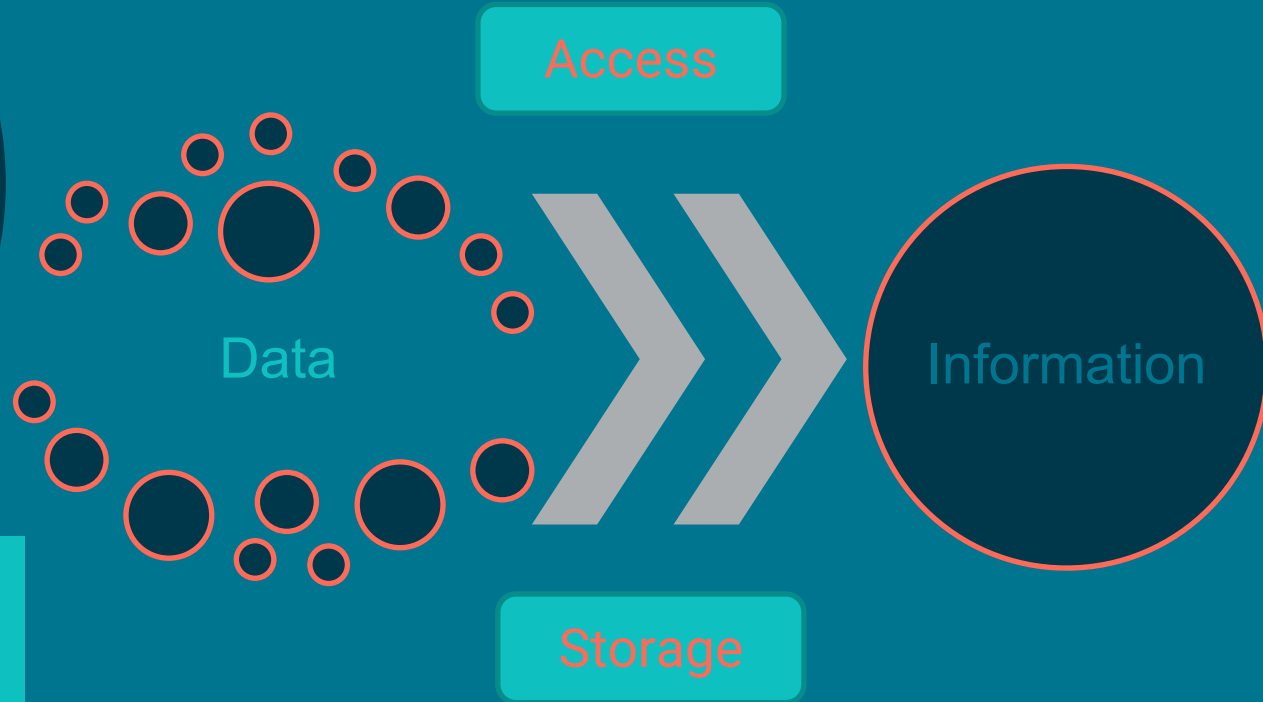

When data is processed, organized, structured or presented in a given context so as to make it useful, it is called information.

Example:

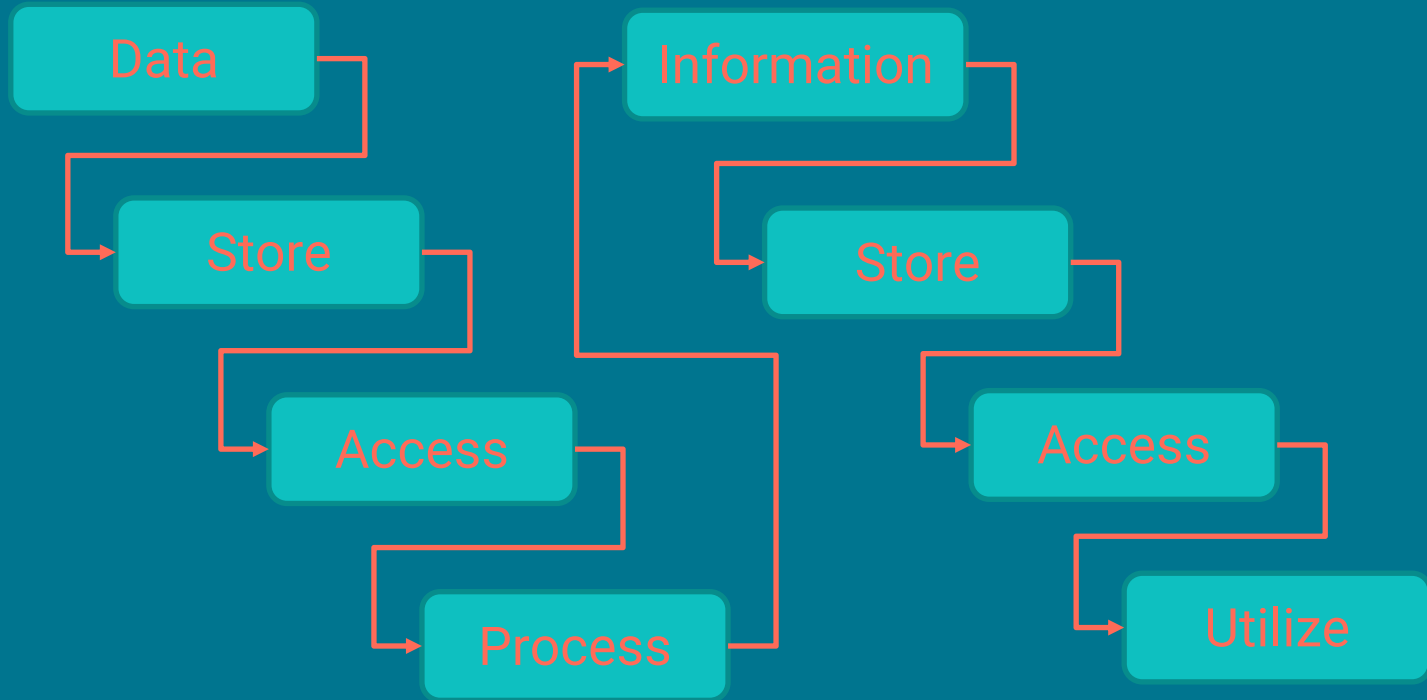

Each student's test score is one piece of data.

The average score of a class or of the entire school is information that can be derived from the given data.

Standards of Data Center – ANSI/TIA-942

Standards of Data Center – ANSI/TIA-942

Tier 1: Basic site infrastructure. A Tier 1 data center offers limited protection against physical events. It has single-capacity components and a single, nonredundant distribution path.

Tier 2: Redundant-capacity component site infrastructure. This data center offers improved protection against physical events. It has redundant-capacity components and a single, nonredundant distribution path.

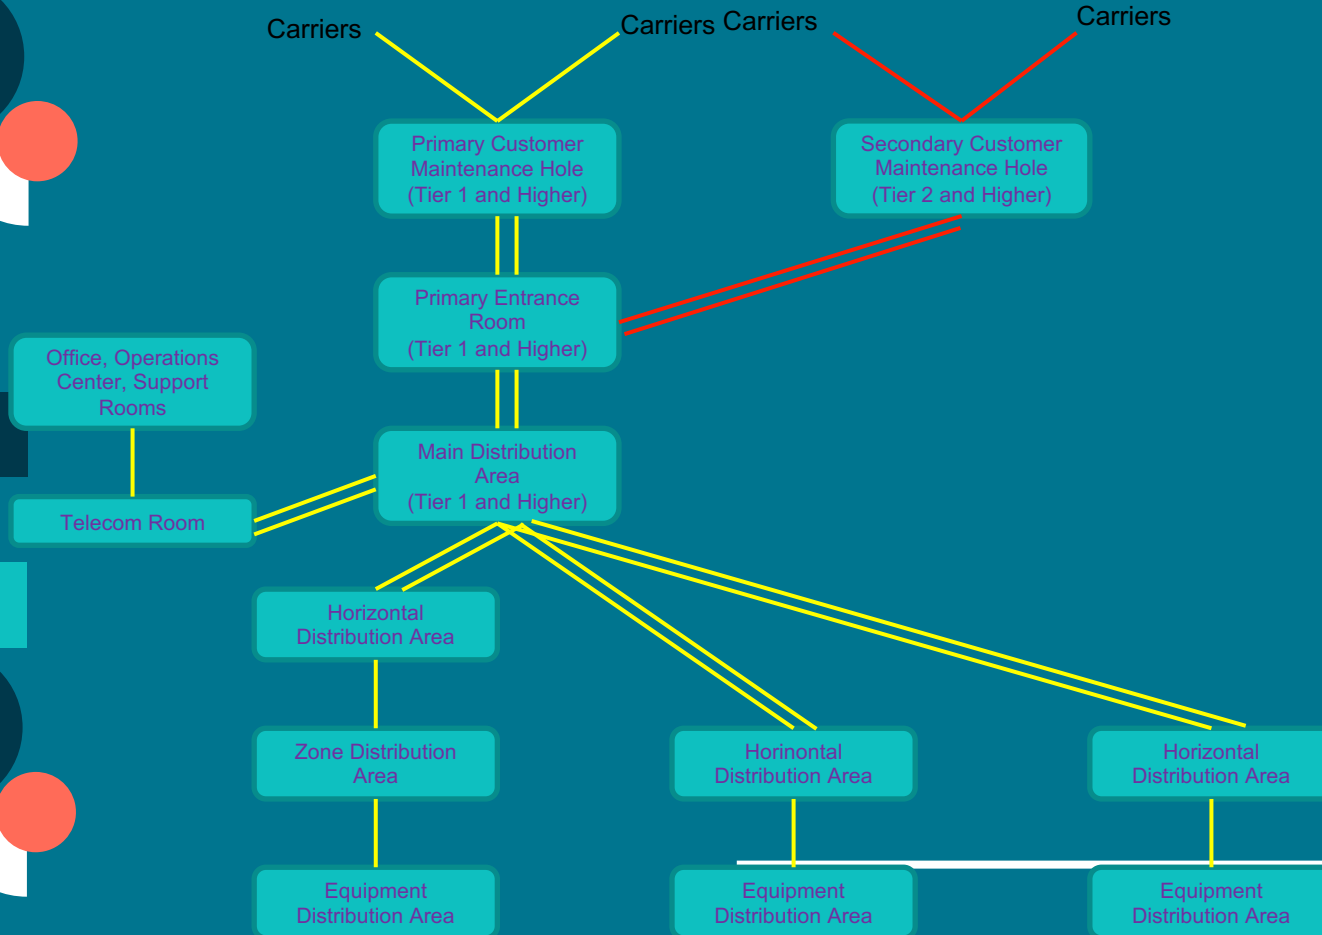

Tier 3: Concurrently maintainable site infrastructure. This data center protects against virtually all physical events, providing redundant-capacity components and multiple independent distribution paths. Each component can be removed or replaced without disrupting services to end users.

Tier 4: Fault-tolerant site infrastructure. This data center provides the highest levels of fault tolerance and redundancy. Redundant-capacity components and multiple independent distribution paths enable concurrent maintainability and one fault anywhere in the installation without causing downtime.

Infrastructure Evolution

Computing infrastructure has experienced three macro waves of evolution over the last 65 years:

The first wave saw the shift from proprietary mainframes to x86-based servers, based on-premises and managed by internal IT teams.

A second wave saw widespread virtualization of the infrastructure that supported applications. This allowed for improved use of resources and mobility of workloads across pools of physical infrastructure.

The third wave finds us in the present, where we are seeing the move to cloud, hybrid cloud and cloud-native. The latter describes applications born in the cloud.

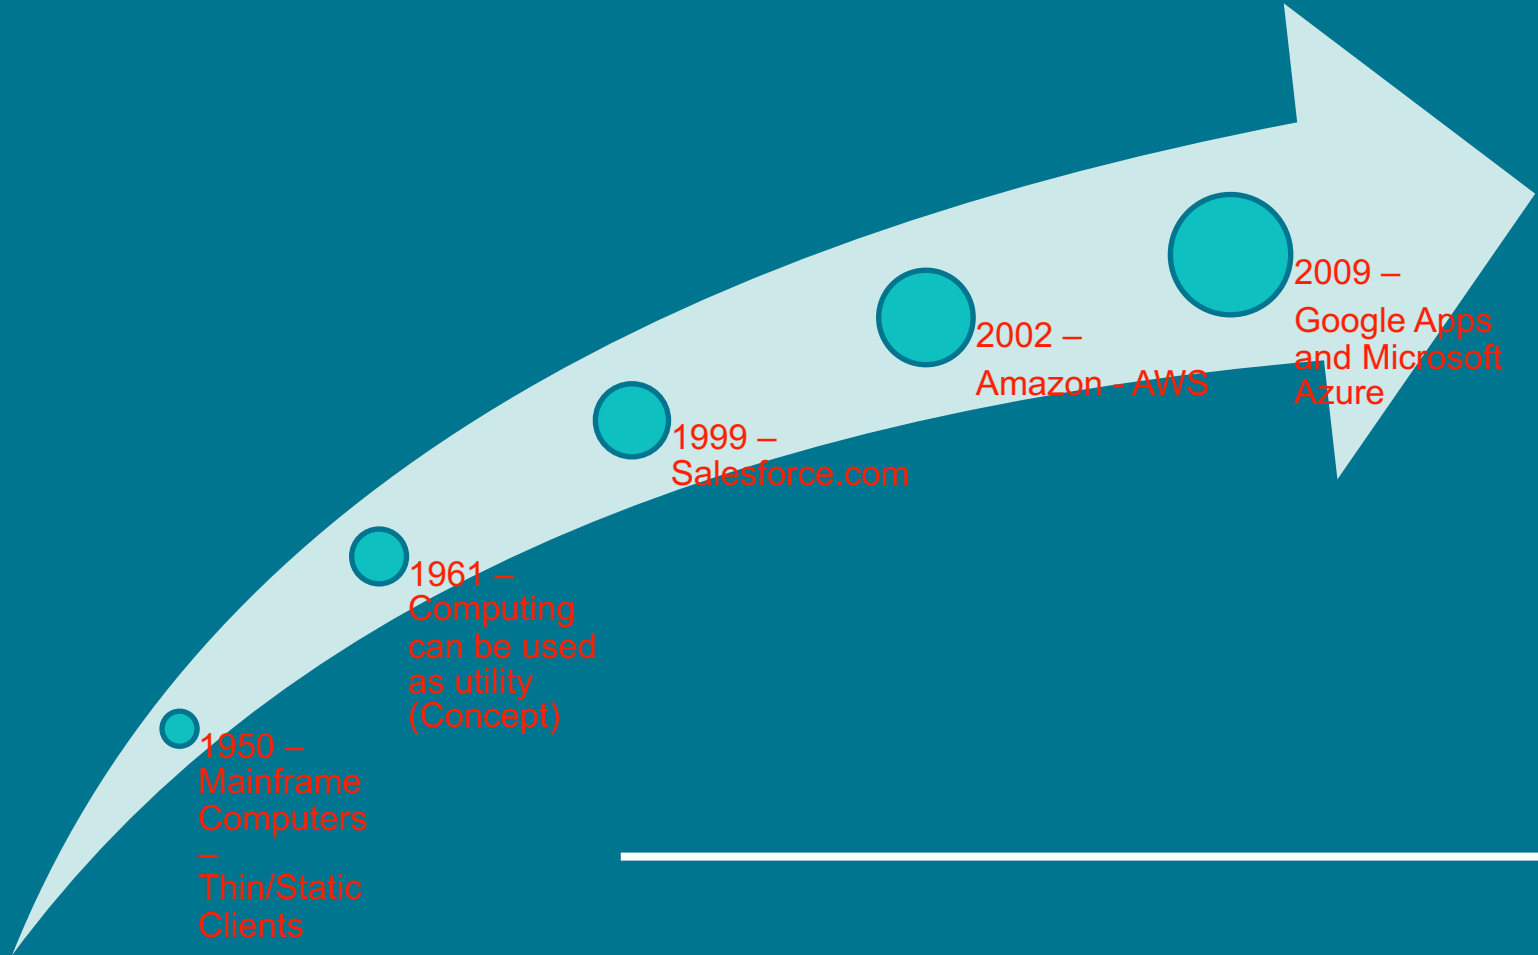

Introduction to Cloud Computing

Cloud computing is not a new technology, but an IT delivery model using existing technology. Its main purpose is to transform computing resources into a utility just like electricity or water, which can be easily accessible and charged according to its use.

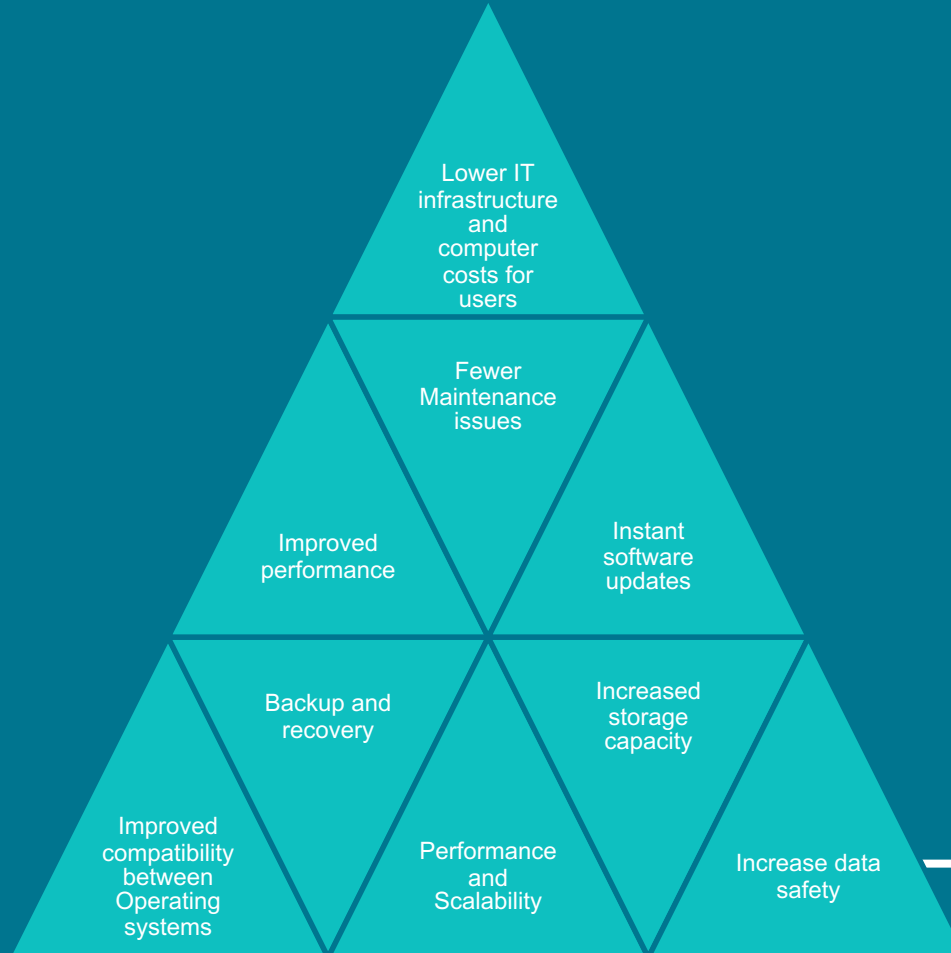

Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction.

Cloud computing implementations provide an extra layer of abstraction (another one!) that hides the complexity of IT implementations and support from its consumers.
